Occupling of a multivariate fraction

Ideas of the algorithm

2

Find a nice/compact form of a fraction

• what does nice/compact mean ?

•
$$a + \frac{b}{c + \frac{d}{e+f}}$$
 or $\frac{ace + acf + ad + be + bf}{ce + cf + d}$
• $cx - \frac{V_{1x}}{k_{1} + x} - \frac{V_{2x}}{k_{2} + x}$ or
 $\frac{ck_{1}k_{2}x + ck_{1}x^{2} + ck_{2}x^{2} + cx^{3} - k_{2}V_{1x} - V_{1}x^{2} - k_{1}V_{2}x - V_{2}^{2}}{(k_{1} + x)(k_{2} + x)}$

Fractions representations

• "expanded" form: numerator / denominator

• tree/dag: + \rightarrow suitable for nested fractions a $\dot{\dot{}}$ b + c $\dot{}$

∃ ⊳

• • • • • • • • • •

A compact form:

- is easier to read and understand for a human
- takes less memory
- may yield a better interval evaluation

- many computer algebra algorithms:
 - operate on polynomials (taking numerators, ...)
 - output polynomials
 - $\bullet~\rightarrow$ Gröbner basis, triangular sets, \ldots
- Multivariate partial fraction decomposition ?
 - Stoutemeyr 2009, "Multivariate partial fraction decomposition"
 - Leinartas 1978 "Factorization of rational functions of several variables into partial fractions"
 - Both approaches decompose a fraction as a sum of fractions, but no nested decomposition is recovered
- finding nested/compact forms for fractions seem quite difficult ...

< □ > < □ > < □ > < □ > < □ >

Occupling of a multivariate fraction

Ideas of the algorithm

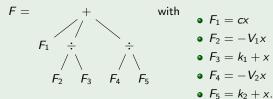

2

Definition

- let F a fraction of $\mathbb{K}(X)$, where X is a set of variables,
- let X_1, \ldots, X_p a partition of the set X,
- *F* can be decoupled w.r.t. to the partition if *F* can be written as $F = A(F_1, F_2, \dots, F_p)$ where :
 - $A(a_1,\ldots,a_p)$ is a tree with nodes $+, \times$ and \div ,
 - each a_i appears at most once (at a leaf),
 - each F_i is a fraction in X_i .

Example

 $X = \{c, V_1, k_1, V_2, k_2\}, \mathbb{K} = \mathbb{Q}(x), F = cx - \frac{V_1 x}{k_1 + x} - \frac{V_2 x}{k_2 + x} \text{ can decoupled w.r.t. the partition } \{c\}, \{V_1\}, \{k_1\}, \{V_2\}, \{k_2\}:$

Properties

- for each fraction F, there exists a (unique) finest partition for decoupling F
- there is no uniqueness for the tree A and the F_i 's

Interest

The more decoupled the fraction is:

- the shorter/more compact/nicer the fraction should look
- the better the interval evaluation should be

A D > A B > A B > A

Example: better "looking" equations

(Example 4 of the paper, self-regulated gene)

$$H'(t) = -G'(t) = \frac{a((fM(t) - V_p)P(t) + fk_pM(t))G(t)}{(aG(t) + aP(t) + b)(k_p + P(t))},$$
$$M'(t) = \frac{(eG(t) - V_m)M(t) + ek_mG(t)}{k_m + M(t)},$$
$$P'(t) = \frac{((fM(t) - V_p)P(t) + fk_pM(t))(aP(t) + b)}{(aG(t) + aP(t) + b)(k_p + P(t))}.$$

becomes

$$H'(t) = -G'(t) = \frac{fM(t) - \frac{V_p P(t)}{k_p + P(t)}}{1 + \frac{\frac{b}{a} + P(t)}{G(t)}}$$
$$M'(t) = -\frac{V_m}{\frac{k_m}{M(t)} + 1} + eG(t) \qquad P'(t) = \frac{fM(t) - \frac{V_p P(t)}{k_p P(t)}}{1 + \frac{G(t)}{P(t)\left(1 + \frac{b}{aP(t)}\right)}}.$$

(Example 5 of the paper)

$$F = \frac{a_0 + \frac{a_1}{b_1 + \frac{a_2}{b_2 + a_3}}}{c_0 + \frac{c_1}{d_1 + \frac{c_2}{d_2 + c_3}}} + \frac{e_0 + \frac{e_1}{f_1 + \frac{e_2}{f_2 + e_3}}}{g_0 + \frac{g_1}{h_1 + \frac{g_2}{h_2 + g_3}}}$$

- developing F yields P/Q with P and Q of degree 10, and more than 200 monomials
- our algorithm retrieves F (up to some signs) from P/Q
- if each variables lies in the interval [1.0, 5.0],
 - the fraction P/Q yields the interval $[0.140 \times 10^{-5}, 0.284 \times 10^{7}]$
 - the decoupled form yields [0.237, 16.8].

Note: this is of course an extreme case scenario

3 Decoupling of a multivariate fraction

Ideas of the algorithm

2

decouple(F,X), where $\overline{F} \in \mathbb{K}(X)$

if F cannot be decoupled for any partition of X then return F

else

find a partition (Y, Z) of X such that F can written as A(G(Y), H(Z)) call decouple(G, Y) and decouple(H, Z) and build the result

How to find the partition (Y, Z)?

イロト イヨト イヨト

If a fraction $F \in \mathbb{K}(X)$ can be decoupled w.r.t. a partition (Y, Z) of X, then F can be written as one the following form:

C1
$$G(Y) + H(Z)$$

C2 $c + G(Y)H(Z)$
C3 $c + \frac{1}{G(Y) + H(Z)}$
C4 $c + \frac{d}{1 + G(Y)H(Z)}$ with

where c and d are in (almost!) \mathbb{K} , and $d \neq 0$.

- the four cases are exclusive
- cases C1 and C2 are sufficient if F is a polynomial
- case C1 amounts to a simple graph traversal
- cases C2,C3,C4 are more difficult: the constants *c* and *d* are computed if they exist, but how ?

Image: A math the second se

Case C2 with differential algebra !

Assume

•
$$f(x,y) = c + g(x)h(y)$$
, with c constant

- x and y are scalar
- f, g and h are smooth enough
- f_{xy} is not the zero function

Then
$$c = f - \frac{f_x f_y}{f_{xy}}$$

With DifferentialAlgebra (Maple package by François Boulier)

Eliminate g and h in the following system

$$f = c + gh \tag{1}$$

$$c_x = c_y = 0 \tag{2}$$

$$g_y = 0 \tag{3}$$

$$h_x = 0 \tag{4}$$

A D > A B > A B > A

э

Over $\mathbb{K} = \mathbb{Q}(a)$, the fraction $p = \frac{xy+a}{x+y}$ in $\mathbb{K}(x, y)$ can be decoupled w.r.t. $\{x\}, \{y\}$:

$$-\sqrt{a} + \frac{2\sqrt{a}}{1 + \left(1 - \frac{2\sqrt{a}}{x + \sqrt{a}}\right)\left(-1 + \frac{2\sqrt{a}}{y + \sqrt{a}}\right)}$$

- if you plug a = 2, then $\mathbb{K} = \mathbb{Q}$ and you get a $\sqrt{2}$
- if you plug a = -1, then $\mathbb{K} = \mathbb{Q}$ and you get a complex I
- no escape is possible ... reason: the constants c and d (case C4) are solutions of a second order equation
- you sometimes need to take radicals to decouple a fraction (this was quite surprising)

- the code requires some heuristics to avoid too many differentiations (many evaluations tricks are used)
- the complexity is polynomial in the number of operations on fractions
